

Computer-System Architecture

- 
- A close-up photograph of several green leaves with numerous water droplets on their surfaces, set against a dark background. The leaves are vibrant green and the droplets are clear and glistening.
- Computer system can be organized in a number of ways and can be categorized roughly according to the number of general-purpose processors used.
 - How a modern computer system works

A close-up photograph of several green leaves with numerous water droplets on their surfaces, set against a dark background. The leaves are vibrant green and the droplets are clear and glistening.

The general-purpose processors are categorized as follows

- 1.)Single-Processor Systems
- 2.)Multiprocessor Systems

- 
- A close-up photograph of several green leaves with numerous water droplets on their surfaces, set against a dark background. The leaves are vibrant green and the droplets are clear and glistening.
- **Single-Processor Systems:**
 - Most computer systems used a single processor.
 - On a single processor system, there is one main CPU capable of executing a general purpose instruction set, including instructions from user processes.

- 
- Almost all single processor systems have other special-purpose processors as well.
 - They come in the form of device-specific processors, such as disk, keyboard, and graphics controllers.
 - on mainframes, they may come in the form of more general-purpose processors, such as I/O processors that move data rapidly among the components of the system

- 
- All of these special-purpose processors run a limited instruction set and do not run user processes.
 - They are managed by the operating system, in that the operating systems ends them information about their next task and monitors their status

- 
- A close-up photograph of several green leaves with numerous water droplets on their surfaces, set against a dark background. The leaves are vibrant green and the droplets are clear and glistening.
- For example, a disk-controller microprocessor receives a sequence of requests from the main CPU and implements its own disk queue and scheduling algorithm.
 - This arrangement relieves the main CPU of the overhead of disk scheduling

- 
- PCs contain a microprocessor in the keyboard to convert the keystrokes into codes to be sent to the CPU.
 - In other systems or circumstances(situation), special-purpose processors are low-level components built into the hardware.
 - The operating system cannot communicate with these processors; they do their jobs autonomously.
 - The use of special-purpose microprocessors is common and does not turn a single-processor system into a multiprocessor

- 
- Multiprocessor Systems: -
 - The multiple-processor systems in use today are of two types.
 - 1. Asymmetric multiprocessing.
 - 2. Symmetric multiprocessing.
 - Asymmetric multiprocessing: in which each processor is assigned a specific task.

- Symmetric multiprocessing (SMP):
- The most common systems use symmetric multiprocessing (SMP), in which each processor performs all tasks within the operating system.

- 
- Multiprocessor Systems:
 - multiprocessor systems also known as parallel systems or multicore systems.
 - Multiprocessor systems have two or more processors in close communication, sharing the computer bus and sometimes the clock, memory, and peripheral devices

1.) Single Processor Systems:-

- Single Processor Systems
 - One CPU
 - May have other special-purpose processors (such as disk controllers)
 - Run a limited instruction set
 - Do not run user processes
 - Sometimes managed by OS
- For example a disk controller processor receives a sequence of requests from the main CPU and implements its own disk queue and scheduling algorithm to relieve the main CPU of the overhead of disk scheduling.

2.) Multiprocessor systems:-

- Two or more processors in close communication, sharing the computer bus and sometimes the clock, memory, and peripherals.
- Advantages:
 - Increased throughput
 - The speed-up ratio with N processors is not N however.
 - Economy of scale
 - Sharing of peripherals, mass storage, power supplies
 - Increased reliability
 - Graceful degradation
 - Fault tolerance
 - Failure detection, diagnose and correction
 - Hardware duplication

- 
- Two types:
 - **Asymmetric multiprocessing** in which each processor is assigned a specific task. A master processor controls the system, scheduling and allocating work to slave processors.
 - **Symmetric multiprocessing (SMP)** in which each processor performs all tasks within the operating system. All processors are peers.
